> #
  # This is a simple factorization
  # procedure using trial division.
  # The result is a sequence of pairs
  # [p,e] where the p's are the prime
  # factors and the e's are the exponents.
  # The factors are anyway in increasing order.
  # Only primes <= P are tried, hence the
  # last "factor" may composite, if
  # it is greater then P^2;
  #

#
# This is a commented version of the Maple procedure
# ifactor for analysis of the methods.
#
# The input parameter n in general a positive integer.
#
# After a parameter cheking other cases: negative
# integer, rational numbers, etc. are treated.
#
# The first step is remove factors 2, 3, 5,7, 11, 13.
# gcd(n,2^4*3^2*5*7*11*13) calculated until became 1.
# If it is greater then 1, then this gcd is factored by
# the small routine ifactor/ifact235.
#
# The second step is remove somewhat larger prime factors below
# from 17 to 1699. This also happens with the gcd trick. Until
the
# gcd is larger then 1, the routine ifactor/ifact1st find these
# factors from the gcd.
#
# If the remainder still greater then 1, then the procedure
# corresponding to the second parameter is loaded until the name
# `ifactor/bottom` and the procedure ifactor/ifact0th called
# with passing thierd and further parameters.
# This procedure use `ifactor/bottom`.
#
# If no second parameter is passed, then the `ifactor/morrbril`
# procedure loaded and the procedure ifactor/ifact0th called.
#

#
# This is the general end-factoring routine.
# The input is a positive integer containing no
# factor below 1700.
#
# If the number is less then 1709^2, then it is
# a prime and simple returned. Otherwise the number is
# tested and if it is found to be prime, returned.
#
# The second step is to try whether the numbers is
# a power using the routine ifactor/power.
#
# The thierd step is to try Pollard's p-1 method.
# If there are chanches then tried again.
# After the second failer or if no chances
# another version called ifactor/pp100000
# called to find factors p for which p-1
# has only factors below 100000.
#
# The last try is the procedure ifactor/bottom,
# which depends on the second input parameter.
#
# Finally, if no factor is found, then the
# routine returns with fail. Otherwise if is called
# for the factors found and returns with the product.

#
# This procedure try to find factors of the input
# positive integer n using Pollard's p-1 method.
# The second parameter is the base to find the
# factors.
#
# The base is in a cycle powered gradually to 2^9,
# 3^6*5^4*7^2*11^2, 7*11*13^2*31^2*1229,
# 17^2*19^2*23^2*37*41*263, 29^2*43*47*53*83*443,
# ... 1699*1733*1741*1811*1867*1907*1913.
# After each step the gcd of the power-1 and n
# is calculated. If the power was not 1, then
# this gcd is returned. If the power was 1,
# i.e. more factor steps in, then the power
# calculation is repeated in smaller steps.
# If this separates the factors, then a factor
# is given back. Otherwise we try again.
#
